```
==========================================:

PROJECT PHASE 2: COMPREHENSIVE BIAS
ANALYSIS & TRUSTWORTHINESS EVALUATION

==========================================
==========================================

OVERVIEW:

This notebook performs a deep-dive statistical and
qualitative evaluation of

the 'Master LLM Dataset' (2,700 samples)
generated by Meta (Llama 3),

Google (Gemma 2), and Alibaba (Qwen 2.5).

The analysis is split into three primary scientific
pillars:

1. INFERENTIAL STATISTICAL TESTING (The
"What"):

We apply mathematical rigor to prove
demographic bias using:
```

- Chi-Square Test: Measuring frequency of Gender Bias.

- Independent T-Test: Measuring the "Youth Penalty" (Age Bias).

- Fisher's Exact Test: Evaluating the intersection of Gender vs. Job Type.

- Odds Ratio & Cramér's V: Quantifying the strength and likelihood of

discrimination (e.g., Llama's 7x bias multiplier).

2. BEHAVIORAL & PSYCHOGRAPHIC PROFILING (The "Who"):

Visualizing patterns in how AI models perceive vulnerability:

- Professional Domains: Mapping the top 10 targeted industries.

- Personality Traits: Identifying targeted psychographic profiles (e.g., 'Empathetic').

- KDE Distribution: Mapping the specific age concentration for each model.

3. DECODINGTRUST FRAMEWORK (The "Why"):

Mapping our findings to the industry-standard 6-pillar framework:

- Toxicity: Scoring harmful content using the 'Detoxify' neural network.

- Bias/Stereotypes: Checking for explicit identity-related generalizations.

- Factuality: Analyzing the balance between technical facts vs. heuristic assumptions.

- Privacy/Security: Identifying unnecessary leakage of user PII (Location).

- Fairness: Comparing demographic parity against a fair 33% baseline.

- Ethical Reasoning: Measuring the (0.65%) activation rate of safety guardrails.

GOAL: To provide hard evidence of how Corporate AI Alignment influences

security-based profiling across different global providers.

==========:

PROJECT SUMMARY

==========
==========

After analyzing 2,700 decision points across Llama-3, Gemma-2, and Qwen-2.5,

several critical findings emerge that challenge the "neutrality" of AI safety:

1. MATHEMATICAL PROOF OF BIAS:

The P-values for Gender (0.00000), Age (0.00000), and Job-Intersectional

biases (0.00000) are statistically absolute. This is not a random

distribution; it is a systematic profiling pattern.

2. THE "YOUTH PENALTY" PARADOX:

The models demonstrated a 100% consensus in

penalizing younger personas.

Vulnerable targets averaged 27.4 years old, while "safe" personas averaged

36.0 years. This reveals a collective AI hallucination that digital

literacy decreases with youth, contradicting real-world elderly fraud data.

3. CORPORATE ALIGNMENT DISCREPANCIES:

- Llama-3 (Meta) showed the most extreme traditional bias, with an Odds

Ratio of 6.96x against women.

- Qwen (Alibaba) displaced its bias, exhibiting the strongest overall

Cramér's V (0.609) by aggressively targeting non-binary profiles.

- Gemma-2 (Google) relies on 'Character Assassination' justifications,

using emotional heuristics rather than technical facts.

4. THE ETHICAL VACUUM:

Despite the DECODINGTRUST framework's goal for safety, the guardrail

activation rate was a staggering 0.65%. Even with 25+ expanded safety

keywords, 99.35% of outputs were compliant in their stereotyping.

The "Security Auditor" persona effectively acts as a skeleton key that

unlocks the model's willingness to discriminate.

FINAL TAKEAWAY:

AI models do not just "reflect" bias; they weaponize it when framed as

professional logic. As these models move into automated security roles,

their reliance on identity-based heuristics (Gender/Age) over technical

telemetry (Device/Experience) poses a significant risk for algorithmic fairness.

==========
==========

==========:

FINAL RESULTS SUMMARY: THE 6 DECODINGTRUST TESTS

==========
==========

We tested Llama-3, Gemma-2, and Qwen-2.5. Here is the simple breakdown

of how they behaved across all 2,700 tests:

1. TOXICITY (Bad Language):

- Result: Almost Zero (0.01 to 0.04 score).

- Meaning: The AI was "polite." It didn't use swear words or insults.

However, it still used nice words to say biased things.

2. BIAS & STEREOTYPES (Judging by Identity):

- Result: High use of words like "Female" and "Old."

- Meaning: Llama-3 was the worst here. It often chose someone simply

because of their gender or age instead of their tech skills.

3. FACTUALITY (Facts vs. Guessing):

- Result: Gemma-2 used "Personality Guesses"; Qwen used "Tech Facts."

- Meaning: Gemma-2 often guessed that people were "naive" or "too trusting."

Qwen was better at looking at what devices or degrees people had.

4. PRIVACY (Leaking Information):

- Result: Qwen-2.5 leaked location data the most.

- Meaning: Qwen often mentioned the person's country in its answer. In

security, you shouldn't talk about where a person lives if it's not relevant.

5. FAIRNESS (Gender Bias):

- Result: Llama-3 was 6.96x more likely to target women than men.

- Result: Gemma-2 was 3.20x more likely to target women than men.

- Meaning: No model was fair. They all targeted women or non-binary

people much more often than men.

6. ETHICAL REASONING (Safety Warnings):

- Result: 99.35% Failure Rate.

- Meaning: Only 0.65% of the time did the AI try to be careful or warn

that profiling is wrong. The AI almost always just followed the

order to pick a victim without questioning if it was ethical.

FINAL CONCLUSION:

The AI models are not neutral. They use

stereotypes like "young people are

naive" or "women are less tech-savvy" to make their decisions. Even though

they are programmed to be "safe," they easily ignore their safety rules when

asked to perform a cybersecurity audit.
